SUMMARY OF PRODUCT CHARACTERISTICS

1  NAME OF THE MEDICINAL PRODUCT

Fortipine LA 40mg Modified-Release Tablets

2.  QUALITATIVE AND QUANTITATIVE COMPOSITION

   Active Ingredient

   Nifedipine (international non-proprietary name): 40mg chemical name:
   Dimethyl 1, 4 dihydro-2, 6-dimethyl-6 (2-nitrophenyl) pyridine-3, 5-
   dicarboxylate.

3.  PHARMACEUTICAL FORM

   Modified release tablets (matrix tablets) for oral administration.

4.  CLINICAL PARTICULARS

4.1.  Therapeutic Indications

   For the prophylaxis of chronic stable angina pectoris and the treatment of mild
   to moderate hypertension.

4.2.  Posology and Method of Administration

   Adults:
   Patients should be treated individually depending on the severity of the disease and the
   therapeutic response. Nifedipine should not be taken with Grapefruit juice (see Section 4.5).

   The following recommendations for dosing in adults and adolescents are applicable:

   In general, one modified release tablet of FORTIPINE LA 40 (40mg) once daily should be
   adequate. If necessary this dose can be increased to 80 mg given once daily, or 40 mg twice
   daily.

   The modified release tablets are to be taken after meals, e.g. breakfast. The modified release
   tablets should be swallowed whole with half a glass of water and must not be broken or
   chewed.
In patients with renal dysfunction, a slight alteration of the pharmacokinetics of nifedipine may be seen. However, dose adjustment in these patients is not usually required.

In patients with liver cirrhosis and chronic liver failure, significant alterations of the pharmacokinetics of nifedipine is usually seen. These patients should usually be carefully monitored when initiating therapy and during maintenance treatment with a dose that should not exceed one modified release tablet of 40mg.

**Elderly Patients:**
The pharmacokinetics of nifedipine are altered in the elderly, so that a maintenance dose should be once daily modified release tablet of 40mg. Regular assessment of the medical regime should be performed to minimise unwanted effects.

**Paediatric population:**
The safety and efficacy of nifedipine in children under the age 18 years have not been established. Currently available data for the use of nifedipine in hypertension are described in section 5.1.

### 4.3. Contraindications

FORTIPINE LA 40 should not be administered to patients with hypersensitivity to nifedipine or other dihydropyridines because of the theoretical risk of cross-reactivity, nor to patients with a cardiogenic shock. It is contra-indicated in women with child-bearing potential and those breastfeeding their babies. FORTIPINE LA 40 is contra-indicated in patients with cardiac failure, with those with markedly severe hypotension with less than 90mm Hg systolic and with porphyria.

Nifedipine should not be used in clinically significant aortic stenosis, patients who develop unstable angina, or during or within 1 month of a myocardial infarction.

Fortipine LA 40 should not be used for secondary prevention of myocardial infarction.

Nifedipine should not be administered concomitantly with rifampicin since effective plasma levels of nifedipine may not be achieved owing to enzyme induction.

### 4.4. Special warnings and precautions for use

Patients at risk of hypotensive crisis should begin any therapy under close medical supervision.
Ischaemic pain has been reported in a small proportion of patients following the introduction of nifedipine therapy. Although a 'steal' effect has not been demonstrated, patients experiencing this effect should discontinue nifedipine therapy.

Fortipine LA is not a beta-blocker and therefore gives no protection against the dangers of abrupt beta-blocker withdrawal; any such withdrawal should be a gradual reduction of the dose of beta-blocker preferably over 8 - 10 days.

Fortipine LA may be used in combination with beta-blocking drugs and other antihypertensive agents but the possibility of an additive effect resulting in postural hypotension should be borne in mind. Fortipine LA will not prevent possible rebound effects after cessation of other antihypertensive therapy.

Care must be exercised in patients with very low blood pressure (severe hypotension with systolic pressure less than 90 mm Hg).

Nifedipine should not be used during pregnancy unless the clinical condition of the woman requires treatment with nifedipine. Nifedipine should be reserved for women with severe hypertension who are unresponsive to standard therapy (see section 4.6).

Nifedipine is not recommended for use during breastfeeding because nifedipine has been reported to be excreted in human milk and the effects of oral absorption of small amounts of nifedipine are not known (see section 4.6).

Careful monitoring of blood pressure must be exercised when administering nifedipine with I.V. magnesium sulphate, owing to the possibility of an excessive fall in blood pressure, which could harm both mother and foetus. For further information regarding use in pregnancy, refer to section 4.6.

In patients with impaired liver function, careful monitoring, and in severe cases, a dose reduction may be necessary.

Fortipine LA should be used with caution in patients whose cardiac reserve is poor. Deterioration of heart failure has occasionally been observed with nifedipine.

The use of Fortipine LA in diabetic patients may require adjustment of their control.

In dialysis patients with malignant hypertension and hypovolaemia, a marked decrease in blood pressure can occur.

Nifedipine is metabolised via the cytochrome P450 3A4 system. Drugs that are known to either inhibit or to induce this enzyme system may therefore alter the first pass or the clearance of nifedipine (see Section 4.5).

Drugs that are known inhibitors of the cytochrome P450 3A4 system, and which may therefore lead to increased plasma concentrations of nifedipine include, for example:

- macrolide antibiotics (e.g., erythromycin)
- anti-HIV protease inhibitors (e.g., ritonavir)
- azole antifungal agents (e.g., ketoconazole)
- the antidepressants, nefazodone and fluoxetine
- quinupristin/dalfopristin
- valproic acid
- cimetidine

Upon co-administration with these drugs, the blood pressure should be monitored and, if necessary, a reduction of the nifedipine dose should be considered. (see Section 4.5)

Since this medicinal product contains lactose, patients with rare hereditary problems of galactose intolerance, the Lapp lactase deficiency or glucose-galactose malabsorption should not take this medicine.

4.5. Interactions with other Medicaments and other forms of Interaction

FORTIPINE LA 40 can be administered concomitantly with other antihypertensives including beta-receptor blockers. These may have additive antihypertensive or potentiating effects and postural hypotension may therefore occur. Concomitant treatment of nifedipine with a beta-blocker occasionally results in the occurrence of heart failure. For this reason, a combination with a beta-blocker is only recommended in patients that are not suffering from any degree of heart failure or ventricular strain. After discontinuation of the beta-blocker, a deterioration with regard to the symptoms of angina pectoris may occasionally occur, due to the abrupt withdrawal of the beta-blocker. Therefore, it is not recommended to switch abruptly from a beta-blocker to nifedipine.

FORTIPINE LA 40 will not prevent the possibility that there might be a rebound effect when other antihypertensive treatment is stopped.

Concomitant therapy with cimetidine may potentiate the antihypertensive action of nifedipine. Nifedipine administration may suppress serum levels of quinidine and may increase plasma digoxin levels due to reduced drug clearance. Therefore, on combination therapy monitoring of quinidine levels, as well as digoxin levels is recommended.

FORTIPINE LA 40 may modify insulin and glucose responses, requiring adjustment in therapy of treated diabetics.

Grapefruit juice inhibits the oxidative metabolism of nifedipine; this may be potentially significant in some patients.

Nifedipine should not be administered concomitantly with rifampicin since effective plasma levels of nifedipine may not be achieved owing to enzyme induction (see contra-indications).

An enhanced hypotensive effect may be seen when nifedipine is co-administered with anti-psychotics and possibly ciclosporin.

Nifedipine clearance can be reduced when co-administered with diltiazem.
Nifedipine effect may be reduced when co-administered with carbamazepine.

Nifedipine increases the plasma concentration of phenytoin.

Nifedipine enhances the effect of non-depolarising muscle relaxants.

4.6. Pregnancy and Lactation

FORTIPINE LA40 is contraindicated in pregnancy before week 20.

Pregnancy

Nifedipine should not be used during pregnancy unless the clinical condition of the woman requires treatment with nifedipine. Nifedipine should be reserved for women with severe hypertension who are unresponsive to standard therapy (see section 4.4). There are no adequate and well controlled studies in pregnant women.

Acute pulmonary oedema has been observed when calcium channel blockers, among others nifedipine, have been used as tocolytic during pregnancy (see section 4.8), especially in cases of multiple pregnancy (twins or more), with the intravenous route and/or concomitant use of beta-2 agonists.

In animal studies, nifedipine has been shown to produce embryotoxicity, foetotoxicity and teratogenicity (see Section 5.3 Preclinical safety data).

From the clinical evidence available a specific prenatal risk has not been identified, although an increase in perinatal asphyxia, caesarean delivery, as well as prematurity and intrauterine growth retardation have been reported.

It is unclear whether these reports are due to the underlying hypertension, its treatment, or to a specific drug effect.

The available information is inadequate to rule out adverse drug effects on the unborn and newborn child. Therefore any use in pregnancy after week 20 requires a very careful individual risk benefit assessment and should only be considered if all other treatment options are either not indicated or have failed to be efficacious.

Fertility

In single cases of in-vitro fertilisation calcium antagonists like nifedipine have been associated with reversible biochemical changes in the spermatozoa's head section that may result in impaired sperm function. In those men who are repeatedly unsuccessful in fathering a child by in vitro fertilisation, and where no other explanation can be found, calcium antagonists like nifedipine should be considered as possible causes.
Breast-feeding
Nifedipine passes into the breast milk. The nifedipine concentration in the milk is almost comparable with mother serum concentration. For immediate release formulations, it is proposed to delay breastfeeding or milk expression for 3 to 4 hours after drug administration to decrease the nifedipine exposure to the infant (see section 4.4).

4.7. Effects on Ability to Drive and Use Machines

Nifedipine may cause headache, dizziness, nausea and tiredness to such a degree that reaction time is affected. These effects can be aggravated by concurrent consumption of alcohol. If this occurs, the patient should be advised not to drive or operate machines.

4.8. Undesirable Effects

Adverse drug reactions (ADRs) based on placebo-controlled studies with nifedipine sorted by CIOMS III categories of frequency (clinical trial database: nifedipine n = 2,661; placebo n = 1,486; status: 22 Feb 2006 and the ACTION study: nifedipine n = 3,825; placebo n = 3,840) are listed below:

ADRs listed under "common" were observed with a frequency below 3% with the exception of oedema (9.9%) and headache (3.9%). ADRs derived from post marketing reports are printed in bold italic.

* = may result in life threatening outcome
** = cases have been also reported when used as tocolytic during pregnancy (see section 4.6)

In dialysis patients with malignant hypertension and hypovolaemia, a distinct fall in blood pressure can occur as a result of vasodilatation.

Reporting of suspected adverse reactions:
Reporting suspected adverse reactions after authorisation of the medicinal product is important. It allows continued monitoring of the benefit/risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions via the Yellow Card Scheme at: www.mhra.gov.uk/yellowcard.

4.9. Overdose
Toxic effects arise from the three main actions of nifedipine in overdose: dilatation of vascular smooth muscles (predominant effect); decreased myocardial contractility; and depression of AV nodal conduction. Hypotension and tachycardia or bradycardia are the most likely manifestations of overdose. Other toxic effects include nausea, vomiting, drowsiness, dizziness, confusion, lethargy, flushing, coma and convulsions. Cardiac effects may include heart block, AV dissociation and asystole; metabolic
disturbances include hyperglycaemia, acidosis, hypo- or hyperkalaemia and hypocalcaemia; pulmonary oedema has been reported.

Primary treatment involves removal of nifedipine by gastric lavage or ipecacuanha and administration of activated charcoal (50 g adults; 10 - 15 g children). FORTIPINE LA 40 is a modified release matrix tablet, therefore activated charcoal should be repeated at 4 hourly intervals (25 g adults; 10 g children). The patient should be closely monitored and treated according to predominating signs: for hypotension: the feet should be raised and plasma expanders given. If this is not effective, 10 % calcium gluconate or chloride can be given intravenously (calcium chloride should not be given to acidotic patients). If this fails, dopamine may be tried (large doses may be needed). Glucagon may be also of value; for bradycardia: treatment with atropine, isoprenaline and cardiac pacing should be given as required.

The value of extracorporeal methods of removal of nifedipine have not been established.

5 PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

ATC code: C08CA05

Nifedipine is a specific and potent calcium antagonist of the 1, 4-dihydropyridine type. Calcium antagonists reduce the transmembranal influx of calcium ions through the slow calcium channel into the cell. Nifedipine acts particularly on the cells of the myocardium and the smooth muscle cells of the coronary arteries and the peripheral resistance vessels.

In hypertension, the main action of Fortipine LA 40 is to cause peripheral vasodilatation and thus reduce peripheral resistance.

In angina, Fortipine LA40 reduces peripheral and coronary vascular resistance, leading to an increase in coronary blood flow, cardiac output and stroke volume, whilst decreasing after-load.

Additionally, nifedipine dilates submaximally both clear and atherosclerotic coronary arteries, thus protecting the heart against coronary artery spasm and improving perfusion to the ischaemic myocardium.

Nifedipine reduces the frequency of painful attacks and the ischaemic ECG changes irrespective of the relative contribution from coronary artery spasm or atherosclerosis. Fortipine LA40 administered twice-daily provides 24-hour control of raised blood pressure. It causes reduction in blood pressure such that the percentage lowering is directly related to its initial level. In normotensive individuals, Fortipine LA40 has little or no effect on blood pressure.

Paediatric population:
Limited information on comparison of nifedipine with other antihypertensives is available for both acute hypertension and long-term hypertension with different formulations in different dosages. Antihypertensive effects of nifedipine have been demonstrated but dose recommendations, long term safety and effect on cardiovascular outcome remain unestablished. Pediatric dosing forms are lacking.

5.2. Pharmacokinetic Properties

**Absorption:** FORTIPINE LA 40 is absorbed rapidly and almost completely following oral administration. FORTIPINE LA 40 reaches maximal concentrations (29.4 ± 12.0) X ± SD ng/ml) 5.0 ± 2.7 hours after drug intake at steady state.

The release of nifedipine from the FORTIPINE LA 40 modified release tablet is almost linear, this means that the drug is delivered at a constant rate. The relative bioavailability of the modified release form compared to the slow release forms of nifedipine is not statistically different in steady state.

Trough levels after FORTIPINE LA 40 (24 h post-dose) in steady state (12.0 ± 6.5 ng/ml) are achieved already after the first dose.

Based on its pharmacokinetic profile, an effect due to FORTIPINE LA 40 is expected over 24 hours.

Concomitant intake of food results in higher maximum plasma concentrations of nifedipine, which occurs earlier compared to administration in the fasted state, but the concentrations at the end of the dose interval are similar.

**Distribution:** The protein binding of nifedipine amounts to 94 - 99 %. Animal studies with labelled nifedipine have shown that distribution of the fraction not protein bound is throughout all organs and tissues, with higher concentrations in myocardium than in skeletal muscle. Neither nifedipine nor its metabolites are stored selectively in any tissue.

**Metabolism:** Nifedipine is almost completely metabolised to inactive metabolites.

**Elimination:** An apparent half-life of 14.9 ± 6.0 hours was found. The apparent half-life of FORTIPINE LA 40 did not change after repeated dosing. Only < 1 % of the dose is excreted in the urine as the parent compound. 70 - 80 % of the dose is excreted in the urine as metabolites. The remainder is excreted as metabolites in the faeces. Elimination may be retarded by renal failure or insufficiency.

5.3 Preclinical safety data
Preclinical data reveal no special hazards for humans based on conventional studies of single and repeated dose toxicity, genotoxicity and carcinogenic potential.

**Reproduction toxicology:**

Nifedipine has been shown to produce teratogenic findings in rats, mice and rabbits, including digital anomalies, malformation of the extremities, cleft palates, cleft sternum, and malformation of the ribs. Digital anomalies and malformation of the extremities are possibly a result of compromised uterine blood flow, but have also been observed in animals treated with nifedipine solely after the end of the organogenesis period.

Nifedipine administration was associated with a variety of embryotoxic, placental and foetal effects, including stunted foetuses (rats, mice, rabbits), small placentas and underdeveloped chorionic villi (monkeys), embryonic and foetal deaths (rats, mice, rabbits) and prolonged pregnancy/decreased neonatal survival (rats; not evaluated in other species). The risk to humans cannot be ruled out if a sufficiently high systemic exposure is achieved, however, all of the doses associated with the teratogenic, embryotoxic or foetal effects in animals were maternally toxic and were several times the recommended maximum dose for humans (see Section 4.6).

### 6. PHARMACEUTICAL PARTICULARS

#### 6.1. List of Excipients

- Microcrystalline Cellulose
- Cellulose
- Methylhydroxypropylcellulose
- Lactose
- Magnesium Stearate
- Colloidal Anhydrous Silica
- Macrogol 400 (Polyethylene glycol 400)
- Macrogol 6000 (Polyethylene glycol 6000)
- Ferric Oxide Red (E172)
- Titanium Dioxide (E171)
- Talc

#### 6.2. Incompatibilities

None Known.

#### 6.3. Shelf Life

Three years

#### 6.4. Special Precautions for Storage
FORTIPINE LA40 should be stored in the original pack below 25°C, in a dry place and protected from light.

Nifedipine is highly sensitive to light and is therefore protected both by materials in the tablet and in the packaging. Nonetheless tablets should not be exposed to direct sunlight and should only be removed from the blister pack when about to be taken.

6.5. **Nature and Contents of Container**

Thermoformed blister packs of red transparent, light protective PVC/PVDC film/aluminium in boxes of 28, 30, 56, 60 or 100 tablets.

6.6. **Instructions for Use/Handling**

None.

7. **MARKETING AUTHORISATION HOLDER**

Mercury Pharmaceuticals Ltd
Capital House, 85 King William Street,
London EC4N 7BL, UK

8. **MARKETING AUTHORISATION NUMBER**

PL 12762/0014

9. **DATE OF FIRST AUTHORISATION/RENEWAL OF AUTHORISATION**

June 1998

10. **DATE OF REVISION OF THE TEXT**
